A study of anion binding behaviour of 1,3-alternate thiacalix[4]arene–based receptors bearing urea moieties†

Shofiu Rahman,a,b Hirotugu Tomiyasu,a Hirote Kawazoe,a Jiang-Lin Zhao,a Hang Cong,c Xin-Long Ni,c Xi Zeng,c Mark R. J. Elsegood,d Thomas G. Warwick,d Simon J. Teat,c Carl Redshaw,c Paris E. Georgioub and Takehiko Yamato*ab

Three novel thiacalix[4]arene receptors 4a–e each with a 1,3-alternate conformation and possessing two urea moieties linking various phenyl groups substituted with either para electron-donating or -withdrawing groups have been synthesized. The binding properties of these receptors were investigated by means of 1H NMR spectroscopy and UV-vis absorption titration experiments using various anions. The structures and complexation energies were also studied by density functional theory (DFT) methods. The results suggested that receptor 4a, which possesses two p-((trifluoromethyl)phenyl ureido moieties, can complex most efficiently in the urea cavity and exhibits high selectivity towards F– and AcO– ions.

Introduction

Calix[n]arenes1 have three-dimensional tuneable shapes and are used as molecular building blocks with potentially many applications in supramolecular chemistry. Thiacalix[4]arenes2,3 are calix[n]arenes in which the phenolic groups are bridged by sulfur atoms instead of methylene groups, and have received much recent attention for potential applications in various fields across chemistry, biology and environmental science. Various anions such as F– (e.g., in dental caries prevention, in inhalation anesthetics and in the treatment of osteoporosis) also play fundamental roles in biological, medicinal, catalysis, and environmental chemistry.4 The design and synthesis of anion-selective receptors5 is more difficult than that of cation-selective receptors. This is due to some unique features of anions such as their much larger sizes in comparison with those of cations, and also due to the large variety of geometries available,6 some anions are spherical (F–, Cl–, Br–, I–) others are trigonal or Y-shaped (AcO–) and others are tetrahedral (H2PO4–), etc. Anion recognition using artificially-designed receptors7 based on calix[n]arenes is an important research topic in the area of supramolecular chemistry. Calix[n]arene urea derivatives are capable of effectively recognizing and sensing important anions via hydrogen-bonding interactions between the anions and the urea NH protons.7,8

Lhoták and co-workers9 have reported anion receptors based on either upper-rim substituted calix[4]arenes or thiacalix[4]arenes which contain two p-nitrophenyl or p-tolyl urea moieties.9a–c,h These anion receptors exhibited effective recognition abilities towards selected anions in common organic solvents. Recently, Kumar and co-workers reported an anion receptor based on a calix[4]arene in a 1,3-alternate conformation and bearing containing two p-nitrophenyl-ureido moieties.10 This compound exhibited strong binding and good selectivity towards Cl– ion due to strong hydrogen bonding between the Cl– ion and the N-H protons, both in THF or chloroform solutions. However, investigations concerning the influence on the acidity of the urea protons by either electron-donating or electron–withdrawing groups located on the p-position of phenyl groups of urea moieties in analogous thiacalix[4]arenes and the binding of various anions have received scant attention.11

In this article, we report the synthesis of three novel thiacalix[4]arene receptors 4a–e with a 1,3-alternate conformation and possessing two urea moieties linking various...
phenyl groups bearing either para electron-donating or electron-withdrawing groups, together with two benzylic groups at the opposite sides of the thiacalix[4]arene cavity. In our studies, the complexation properties of 4α-e towards F−, Cl−, Br−, I−, AcO− and H2PO4− ions were investigated by 1H-NMR spectroscopy (with 4α-e) and UV-vis absorption (with 4a) titration experiments. Furthermore, the structures and complexation energies for all complexes of the receptors 4α-e with various anions were also determined by theoretical studies using DFT methods.

Results and discussion

Synthesis

O-Alkylation of 1,3-alternate-1 was conducted using 2 equivalents of bromoacetamide in the presence of 2 equivalents of Cs2CO3 according to the reported procedure, and afforded the desired 1,3-alternate-2 in 60 % yield.12 The amide reduction of 1,3-alternate-2 was carried out with a large excess of BH3/THF solution, and afforded the desired 1,3-alternate-3 in 65 % yield. The condensation of 1,3-alternate-3 with 2.2 equivalents of the appropriate isocyanate in CH2Cl2 furnished the receptors 4α-e in good yields (Scheme 1). The 1H NMR spectrum of receptors 4α-e in CDCl3 exhibits the characteristics of a 1,3-alternate conformation such as two singlets (18H each) for the tert-butyl protons, two triplets (4H each) for the OCH2CH2 protons, two singlets (4H each) for the aromatic protons and two singlets (2H each) for the four urea NH protons. Moreover, concentration dependence of the 1H NMR chemical shifts of the urea protons in receptor 4a was not observed (Fig. S11). This (lack of) observation indicates that receptor 4a has strong intramolecular hydrogen bonds between the two urea groups linking the p-(trifluoromethyl)phenyl moieties. The molecular structure of receptor 4a was also verified by X-ray crystallographic analysis (Fig. 1, S12). Receptor 4a was recrystallized from a mixture of CHCl3–CH2CN (3:2, v/v) by slow evaporation. These results indicate that receptor 4a adopts the 1,3-alternate conformation in the solid state. In case of receptor 4a, there are four thiacalixarenes, two Cl− ions, two tetrabutylammonium ions, one chloroform and two acetonitrile molecules in the asymmetric unit. Interestingly, it was found that the two urea groups approach each other and are oriented in parallel due to the existence of dual intramolecular hydrogen bonding (in the case of receptor 4α, for the molecule shown: N(3)–H(3)···O(5) 2.13(3); N(4)–H(4)···O(5) 2.17(3) Å; for the second molecule: N(1A)–H(1A)···O(6A) 2.15(3), N(2A)–H(2A)···O(6A) 2.20(3) Å; for the third molecule: N(3B)–H(3B)···O(5B) 2.30(3), N(4B)–H(4B)···O(5B) 2.17(2) Å; for the fourth molecule: N(1C)–H(1C)···O(6C) 2.31(3), N(2C)–H(2C)···O(6C) 2.27(3) Å) (Fig. 1, S12). Moreover, in the case of receptor 4α, pairs of calixarene molecules are linked via four H-bonds between two urea NH moieties on each calixarene and Cl− ion.

Fig. 1 X-ray crystal structure of receptor 4αCl. H-bonds shown as dashed lines. One of four similar molecules in the asymmetric unit is shown in two orientations rotated by approx. 90°. H atoms not involved in H-bonding, minor disorder components, and solvent of crystallization are omitted for clarity. Guest used: tetrabutylammonium (TBA) salt.

Scheme 1 Synthesis of receptors 1,3-alternate-4α-e.
The binding properties of receptors 4a–e in the presence of various anions as their tetrabutylammonium (TBA) salts, in CDCl₃–CD₂CN (10:1) solution, were investigated by means of ¹H-NMR spectroscopic experiments. As shown in Fig. 2, for the complexation of F⁻ ion with receptor 4c, the signals for the NH₃ protons (red) progressively shifted downfield by 4.55 ppm (δ = 7.35 to 11.9 ppm) until five equivalents of F⁻ ion was added. On the other hand, the signals for the NH₃ protons (blue) progressively shifted downfield by 3.88 ppm (δ = 5.72 to 9.60 ppm) until five equivalents of F⁻ ion were added. These results are strongly suggestive of F⁻ ion recognition by receptor 4c via hydrogen–bonding interactions between the F⁻ ion and the N–H protons. The titration curves shown in Fig. 2, 3 (for 4c) and Fig. S13–S49 show that further addition of various anions to the solution of each receptors 4a–e in CDCl₃ solution, resulted in clear downfield shifts of the ¹H NMR signals of the NH₃ protons. All of the results obtained clearly suggest that anion recognition by the receptors is via hydrogen-bonding interactions between the anion and the NH protons. In particular, as shown in Fig. 2, receptor 4c exhibited the highest selectivity amongst all of the anions tested, toward F⁻ and AcO⁻ ions. Kₐ values for receptors 4a–e and the anions tested were determined by ¹H NMR spectroscopic titration experiments.¹³a (Table 1). These results suggest that the Kₐ values are influenced by the electron-donating or electron-withdrawing groups located at the p-position of the phenyl group.

a Measured in CH2Cl2; at 298 K by UV–vis titration method (Fig. S50–S58); host concentration was 2.5 μM. b Guests used: TBA salts.

ureido moieties. The Ks values for 4, having the electron-withdrawing CF3 groups on the phenyl ureido moieties, were greater than those for the other two receptors. The Ks values for 4, which had the electron-donating CH2 groups on the ureido phenyl moieties were lower than those for 4, and 4. Therefore, the introduction of electron–withdrawing groups at the p-position of the phenyl ureido groups appears to increase the acidity of the urea protons, and hence enhance the anion-binding ability through hydrogen-bonding interactions. Furthermore, receptor 4, had the highest Ks values of all three receptors with each of the anions tested and also had the most effective recognition ability toward F− and AcO− ions. Further complexation studies of 4, with F−, Cl−, AcO− and H2PO4− ions were carried out using UV–vis spectroscopic titration experiments. Receptor 4, (2.5 μM) exhibits a broad absorption band at 295 nm in its UV–vis absorption spectrum. Upon addition of F− ion (0−50 μM) to the solution of 4, Fig. 4 reveals a gradual decrease in the absorption of the band at 288 nm with a simultaneous increase in the absorption at 320 nm and a clear isosbestic point at 295 nm. From the above, it is clear that receptor 4, bearing the CF3 groups has the most effective recognition ability toward F− ions. A Job’s plot for the binding between the receptor 4, and F− ion reveals a 1:1 stoichiometry (Fig. S52), and the Ks for the complexation13b of receptor 4, with F− ion was determined to be 465,405±32,578 M−1 by the UV–vis titrations in CH2Cl2 solution (Fig. S51). These results strongly suggested that F− ion recognition by receptor 4, was via a hydrogen-bonding interaction between F− ion and NH protons, as shown in Fig. 4. The Ks values obtained by similar UV–vis titration experiments of 4, with the other anions are summarized in Table 2.

To further investigate the binding properties of receptors 4a−c with the anions tested, a computational study was carried out. The individual structures for all studies in the gas-phase were fully geometry-optimized using Gaussian 0914 with the B3LYP level of DFT and the 3-21G basis set. Significant changes were observed for the distances between two urea NH moieties on each of the receptors 4a−c in their anion complexes. The conformation changes for 4, upon 1:1 complexation with F− ion can be seen in Fig. 5 (more precise details for the computation studies for receptors 4a−c with the different anions are shown in Fig. S59–S94). Fig. 5 shows the computed structure (right) of the 1:1 complex of 4, with F− ion. Because of the hydrogen-bonding between the F− ion and two urea NH protons, distances between two urea NH moieties (NH1−NH and NHb−NHb) on two p-(trifluoromethyl)phenyl ureido moieties decrease from 8.783 to 2.530 (Å) and from 8.379 to 3.251 (Å), respectively. This also strongly supports the experimental evidence obtained for the formation of a 1:1 (4,−F−) complex. The calculated complexation energies (ΔE kJ mol−1) for receptors 4a−c with the anion complexes are shown in Table 3. The trend for the complexation energies for 4a−c are in the order: F− > AcO− > H2PO4− > Cl− > Br− > I−, which is in agreement with the trend observed for the observed complexation data obtained by means of 1H NMR spectroscopy and UV–vis absorption titration experiments.

Conclusion

In summary, three novel receptors 4a−c bearing a thiacalix[4]arene in a 1,3-alternate conformation have been synthesized. These receptors possess two urea moieties linking various aryl groups bearing electron-donating or -withdrawing groups at their p-positions, which act as anion-binding sites and two benzyl groups at the opposite side of thiacalix[4]arene cavity. The binding of various anions at the two urea moieties was investigated by using 1H NMR, UV–vis absorption titration experiments. It was found that receptor 4, has a much higher
Experimental Section

General

All melting points were determined with a Yanagimoto MP-S1 melting point apparatus. 1H-NMR spectra were determined at 300 MHz with a Nippon Denshi JEOL FT-300 NMR spectrometer with TMS as an internal reference; J-values are given in Hz. UV-vis spectra were measured with a Shimadzu 240 spectrophotometer. Mass spectra were obtained on a Nippon Denshi JMS-01SG-2 mass spectrometer at an ionization energy of 70 eV using a direct inlet system through GLC. Elemental analyses were performed by Yanaco MT-5.

Materials

Unless otherwise stated, all other reagents used were purchased from commercial sources and were used without further purification. Compounds 1,11d,12 212 and 312 were prepared following the reported procedures.

Preparations

4a: To a solution of compound 3 (150 mg, 0.166 mmol) in CH2Cl2 (10 mL) was added phenyl isocyanate (44 mg, 0.37 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with CH2OH to give receptor 4a as a white solid. Recrystallization from CHCl3–CH2OH (2:1) gave receptor 4a (146 mg, 72 %) as a white solid. M.p. 200–202 °C. IR: [1H]NMR (300 MHz, CDCl3); δ = 0.85 (18H, s, tBu × 2), 1.22 (18H, s, tBu × 2), 3.05 (4H, br, CD2NH × 2), 4.01 (4H, br, OCH2 × 2), 5.08 (4H, s, OCH2 × 2), 5.56 (2H, s, NH × 2), 6.90–7.22. (20H, m, Phenyl–H× 20), 7.09 (4H, s, Ar–H× 4), 7.18 (2H, s, NH × 2) and 7.41 (4H, s, Ar–H× 4) ppm. 13C NMR (100 MHz, CDCl3); δ = 30.9 (CH2), 31.0 (CH2), 33.9 (CH2), 34.1 (CH2), 40.9 (CH3), 70.8 (OCH2), 72.0 (OCH2), 124.6 (ArC), 125.9 (ArC), 126.2 (ArC), 126.3 (ArC), 126.5 (ArC), 126.7 (ArC), 128.0 (ArC), 128.3 (ArC), 128.5 (ArC), 128.6 (ArC), 128.8 (ArC), 129.0 (ArC), 129.1 (ArC), 129.3 (ArC), 130.0 (ArC), 132.0 (ArC), 135.2 (ArC), 142.8 (ArC), 146.1 (ArC) and 155.4 (CO) ppm. FABMS: m/z: 1224.50 (M+). C27H28N4O8Si4 (1224.50): calc C 70.55, H 6.58, N 4.57. Found: C 70.52, H 6.57, N 4.58.

4b: To a solution of compound 3 (150 mg, 0.166 mmol) in CH2Cl2 (10 mL) was added p-tolyl isocyanate (48 mg, 0.37 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with CH2OH to give receptor 4b as a white solid. Recrystallization from CHCl3–CH2OH (3:1) gave receptor 4b (146 mg, 70 %) as white solid. M.p. 203–204 °C. IR: [1H]NMR (300 MHz, CDCl3); δ = 0.82 (18H, s, tBu × 2), 1.22 (18H, s, tBu × 2), 2.29 (6H, s, CH3 × 2), 3.06 (4H, br, CH2NH × 2), 4.03 (4H, br, OCH2 × 2), 5.05 (4H, s, OCH2 × 2), 5.50 (2H, br, NH × 2), 6.86 (2H, s, NH × 2), 6.96–7.18. (18H, m, Phenyl–H× 18), 7.10 (4H, s, Ar–H× 4) and 7.41 (4H, s, Ar–H× 4) ppm. 13C NMR (100 MHz, CDCl3); δ = 20.0 (CH3), 31.3 (CH3), 34.3 (CH2), 39.4 (CH2), 70.1 (OCH3), 71.3 (OCH3), 119.8 (ArC), 121.9 (ArC), 125.1 (ArC), 125.2 (ArC), 125.4 (ArC), 125.9 (ArC), 126.2 (ArC), 126.5 (ArC), 127.1 (ArC), 127.5 (ArC), 127.8 (ArC), 128.0 (ArC), 128.3 (ArC), 128.5 (ArC), 128.6 (ArC), 128.8 (ArC), 129.0 (ArC), 129.1 (ArC), 129.3 (ArC), 130.0 (ArC), 135.1 (ArC), 136.2 (ArC), 147.8 (ArC), 148.0 (ArC), 149.5 (ArC), 151.9 (ArC), 154.0 (ArC) and 158.4 (CO) ppm. FABMS: m/z: [M+H]+ Calc'd for C27H28N4O8Si4 (1253.5352) ; Found 1253.5412.

4c: To a solution of compound 3 (150 mg, 0.166 mmol) in CH2Cl2 (10 mL) was added p-(trifluoromethyl)phenyl isocyanate (68 mg, 0.366 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with CH2OH to give receptor 4c as a white solid. Recrystallization from CHCl3–CH2OH (3:2) gave receptor 4c (147 mg, 65%) as a white solid. M.p. 210–211 °C. IR: [1H]NMR (300 MHz, CDCl3); δ = 0.82 (18H, s, tBu × 2), 1.19 (18H, s, tBu × 2), 3.12 (4H, br, CH2NH × 2), 4.03 (4H, br, OCH2 × 2), 5.08 (4H, s, OCH2 × 2), 5.75 (2H, s, NH × 2), 6.92–7.30. (18H, m, Phenyl–H× 18), 7.13 (4H, s, Ar–H× 4), 7.33 (2H, s, NH × 2) and 7.41 (4H, s, Ar–H× 4) ppm. 13C NMR (100 MHz, CDCl3); δ = 32.1 (CH3), 35.6 (C(CH3)3), 40.0 (CH3), 70.1 (OCH2), 70.9 (OCH2), 118.1 (ArC), 118.8 (ArC), 122.2 (ArC), 122.4 (ArC), 122.7 (ArC), 122.9 (ArC), 123.0 (ArC), 123.3 (ArC), 123.6 (ArC), 124.0 (ArC), 124.4 (ArC), 124.8 (ArC), 126.1 (ArC), 126.5 (ArC), 126.8 (ArC), 127.3 (ArC), 127.8 (ArC), 128.0 (ArC), 128.7 (ArC), 129.3 (ArC), 129.5 (ArC), 138.2 (ArC), 138.9 (ArC), 149.2 (ArC), 155.2 (ArC) and 160.7 (CO) ppm. FABMS: m/z: 1361.4861 [M+H]+. C27H28F2N4O8Si4 (1361.4787): calc C 65.27, H 5.77, N 4.11. Found: C 65.32, H 5.75, N 4.08.

Determination of the association constants

The association constants (Ka) were determined by using 1H NMR spectroscopic titration experiments with a constant concentration of host receptor (4.0 × 10−3 M) and varying the guest concentrations (0–8.0 × 10−3 M). The 1H NMR chemical shifts of the urea protons (NH) signal were used as a probe. The Ka values for the complexes of receptor 4ac were calculated by nonlinear curve-fitting analysis of the observed chemical shifts of the NH protons according to the literature procedure.13a

1H NMR titration experiments

A solution of Bu4NX (X = F, Cl, Br, I, AcO, H3PO4) in CD3CN (4.0 × 10−3 M) was added to a CDCl3 solution of receptor 4ac in an NMR tube. 1H NMR spectra were recorded after addition of
the reactants and the temperature of the NMR probe was kept constant at 27 °C.

**Crystallographic analyses of 4a**

Diffraction data were collected on a Bruker APEX 2 CCD diffractometer equipped with graphite-monochromated Mo-Kα radiation at 150(2)°K. Data were corrected for Lorentz and polarisation effects and for absorption. The structures were solved by direct methods and refined by full-matrix least-squares methods, on F2. The asymmetric unit contains four calixarenes two chloride anions, two tetrabutylammonium cations, one chloroform and two acetonitrile molecules of crystallisation. Within each of the four calixarenes there are pairs of N-H···O hydrogen bonds between urea moieties to a single carbonyl O atom. Looking down on the S4 square-shaped planes of the four unique calixarenes, three are approximately geometrically aligned in parallel while one, containing S1(1A), is slightly twisted.

Two tBu groups on calixarenes were modelled as disordered over two sets of positions for the Me groups. See tables for the occupation factors. Two n-butyl chains in the cations exhibit some signs of disorder, but this was not modelled. The chloroform molecule was modelled as fully disordered over two sets of positions. There are two molecules of acetonitrile of crystallisation which reside in calixarene clefts on molecules containing S(1) and S(1B).

Pairs of calixarene molecules are linked via four H-bonds between both urea N-H moieties on each calixarene and a chloride ion. n-butyl ammonium cations reside close to the chloride anions, due to electrostatic attraction. So, each pair of calixarenes is able to capture one chloride ion. The overall packing type is in layers.

Crystal data for 4a: C144H160N60O12S8C48H36N8Cl8·0.5(CHCl3)·C2H5N, M = 2829.91. Triclinic, space group P 1, α =15.1315 (5), b = 28.8618 (11), c = 35.9491 (13) Å, V = 15113.8 (9) Å³. Z = 4, Dc = 1.244 g·cm⁻³, F(000) = 6044, T = 100 K, χ(Mo-Kα) = 0.226 cm⁻¹, χ(Fe-Kα) = 0.71073 Å, colourless crystal of size 0.16 × 0.13 × 0.04 mm. The total number of reflections measured, to θmax = 25.3°, was 42128 of which 27707 were unique (Rint = 0.062); 8953 were ‘observed’ with I > 2σ(I). For the ‘observed’ data only, R1 = 0.068; wR2 = 0.185 for all 42128 reflections and 3705 parameters. Residual electron density within σ−0.86 eÅ⁻³.

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication number CCDC 1062186 for 4a. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: 144-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk].
