To the Editor:

Bronchodilator reversibility (BDR) is a hallmark feature of asthma. In a recent publication Quanjer et al.,<sup>1</sup> raise two valuable points to consider in the interpretation of BDR:

- i. the current ERS/ATS criteria for BDR<sup>2</sup>, i.e., >12% and >200 ml increase in FEV<sub>1</sub> and/or FVC, leads to a bias in that the likelihood of BDR increases with deteriorating pulmonary function. Consequently, the authors propose new criteria for BDR that is based on z-scores, which eliminates this artefact;  $\Delta z\text{FEV}_1 > 0.78$  or  $\Delta z\text{FVC} > 0.64$ .
- ii. FVC BDR, unlike FEV<sub>1</sub> BDR, increases with asthma severity and hence FVC BDR should be interpreted independently to FEV<sub>1</sub> BDR.

We applied the newly proposed BDR criteria to the U-BIOPRED adult asthma cohort<sup>3</sup> to; i) determine the influence of these new criteria on the prevalence of BDR and, ii) explore the difference in clinical characteristics between individuals with FEV<sub>1</sub> BDR and FVC BDR. Four-hundred and ninety-nine asthmatics underwent BDR testing. GLI-2012 reference equations were used to calculate z-scores<sup>4</sup>. Full methodology is presented elsewhere<sup>3</sup>.

Using the ERS/ATS BDR criteria<sup>2</sup>, 55% of the asthma cohort displayed BDR. The re-evaluation of BDR using  $\Delta z\text{FEV}_1 > 0.78$  or  $\Delta z\text{FVC} > 0.64$ , resulted in the reclassification of 12% of the population; 9% no longer having BDR and 3% now fulfilling BDR criteria. A further 10% with BDR changed classification on the type of BDR they displayed (Figure).

We compared the clinical characteristics between the new BDR classifications. Individuals with FVC BDR only and both FEV<sub>1</sub> and FVC BDR had worse lung function, higher BMI and poorer asthma control and quality of life compared to individuals with FEV<sub>1</sub> BDR only (Table).

## Conclusion

The z-score represents how many standard deviations the measured value is away from the mean predicted value, and in spirometry it is used to adjust for age, gender, ethnicity and height<sup>4</sup>. Recently, new criteria for the classification of BDR based on z-scores were proposed, which overcome bias from baseline pulmonary function values<sup>1</sup>. These new criteria influenced the BDR classification in nearly one quarter of the U-BIOPRED adult asthma cohort. Given that we observed

significant differences in clinical characteristics between BDR classifications, our results substantiate the proposal that FVC BDR and FEV<sub>1</sub> BDR should be considered independently. We strongly believe that the important work of Quanjer et al.,<sup>1</sup> should be taken into account when reviewing the guidelines on BDR interpretation.
